A naive approach to quantum transport

Antoine Levitt (INRIA, Paris)

Abstract: I will highlight some classical but sometimes unclear or paradoxical aspects of the computation of transport properties of perfect, periodic quantum systems in the independent electron approximation. In particular, I will review the derivation of the Kubo formula, the definition of conductivity in non-dissipative quantum systems, the effective mass of metals, and the residual conductivity of graphene.

This is based on a joint project with E. Cancès, C. Fermanian and S. Siraj-Dine.
